

Copilot Support Workflow Hub

An end-to-end conversational support automation pattern that turns an employee request into a routed, traceable, and measurable service case.

Sanitized implementation portfolio

What it demonstrates

Copilot Studio topics, Azure AI intent routing, Power Automate orchestration, Dataverse-style case management, Adaptive Cards, human handoff, and operational reporting.

Design objective

Reduce repetitive support work while preserving validation, confidence checks, escalation paths, auditability, and feedback loops for L2/L3 teams.

From conversation to resolution

Support requests often arrive as incomplete messages. This design gives Copilot enough structure to ask the right follow-up questions, route the request with a confidence score, create a consistent case record, and involve a person when automation should stop.

Business outcome: a repeatable support intake and handoff process with clearer ownership, better context for agents, and data that can be reported on instead of being lost in chat history.

Workflow at a glance

Reference architecture

```
Employee / Teams / Web Chat
|
v
Copilot Studio topics
| guided questions + topic routing
v
Intent router (Azure AI / Azure OpenAI pattern)
| intent + confidence + entities
v
Power Automate orchestration
| validate -> create/update -> notify
v
Dataverse-style case + event tables
| status, owner, SLA, audit trail
v
Adaptive Card -> Support queue -> Power BI telemetry
```

Core components

- **Copilot Studio:** topics, entities, fallback, guided dialogue.
- **Power Automate:** validation, branching, integration, notifications.
- **Dataverse:** cases, conversation events, handoff packets.
- **Azure AI:** intent classification and confidence-aware routing.
- **Power BI / Fabric:** volume, resolution, SLA, and escalation reporting.
- **Adaptive Cards:** actionable review and approval experience.

Traceable case lifecycle

How each request is processed

STAGE 1 CONVERSATION

Copilot topic and entity capture

The agent recognizes access requests, case-status questions, knowledge lookups, and requests for a human agent. It asks for missing requester, system, urgency, and business-impact details before calling automation.

Output: normalized request payload

STAGE 2 AI ROUTING

Intent, entities, and confidence

The intent router returns a recommended route and confidence score. High-confidence requests continue automatically; low-confidence or sensitive requests are marked for human review.

Output: intent + confidence + required entities

STAGE 3 AUTOMATION

Power Automate validation and case creation

Workflow branches validate required fields, apply priority rules, generate a case identifier, write the case and conversation event, and notify the assigned queue with an Adaptive Card.

Output: case record + owner + SLA target

STAGE 4 ESCALATION

Context-rich human handoff

When the bot cannot safely resolve the request, the handoff packet includes the conversation summary, extracted entities, confidence score, attempted actions, attachments, and reason for escalation.

Output: L2/L3-ready handoff packet

STAGE 5 TELEMETRY

Feedback and operational reporting

Resolution status, satisfaction rating, response time, topic performance, and escalation reason are captured for Power BI or Microsoft Fabric-style reporting and continuous improvement.

Output: measurable service performance

Example request payload

```
{ "requester": "employee@example.com", "message": "I need viewer access to the reporting workspace", "intent": "access_request", "confidence": 0.92, "priority": "medium", "required_entities": ["workspace", "access_level"], "route": "approval_flow" }
```

Portfolio evidence

- Copilot topics for access requests, case status, and fallback/handoff.
- Power Automate-style JSON for intent routing, case creation, human handoff, and telemetry.
- Dataverse-style data model for cases, events, handoff packets, and feedback.
- Adaptive Card definition for queue review and approval.
- Sample test scenarios and deployment runbook.
- Sanitized UI preview showing how support teams monitor the solution.

Role-aligned capability matrix

Capability	Evidence in this project	Tools / keywords
Conversational AI	Topic design, guided questions, fallback strategy, intent and entity capture.	Copilot Studio, chatbot design, dialog routing
Integration and orchestration	Structured payloads, validation, branching, case creation, queue notifications.	Power Automate, REST/API patterns, JSON
Azure AI and routing	Confidence-aware classification with a human-review threshold.	Azure OpenAI, CLU concepts, intent routing
Application and data	Case lifecycle, event trail, handoff packet, and operational data model.	Dataverse, Power Apps, SQL concepts
Reporting and support	Resolution, SLA, escalation, feedback, and topic-performance telemetry.	Power BI, Fabric-style reporting, L2/L3 support
